Test results show that study participants possess significant telepathic abilities

After thousands of ESP tests with people around the world, the results clearly demonstrate that telepathy is a very real phenomena. The scoreboard leaders have consistently achieved test results in excess of 100-to-1 odds, and over 90% of all participants scored many multiples above chance during extensive testing. In addition, multi-sensory stimuli has been shown to increase scores over 300% compared to control tests where no stimuli was used.

Multi-sensory stimulation during tests increases telepathy scores by over 300%

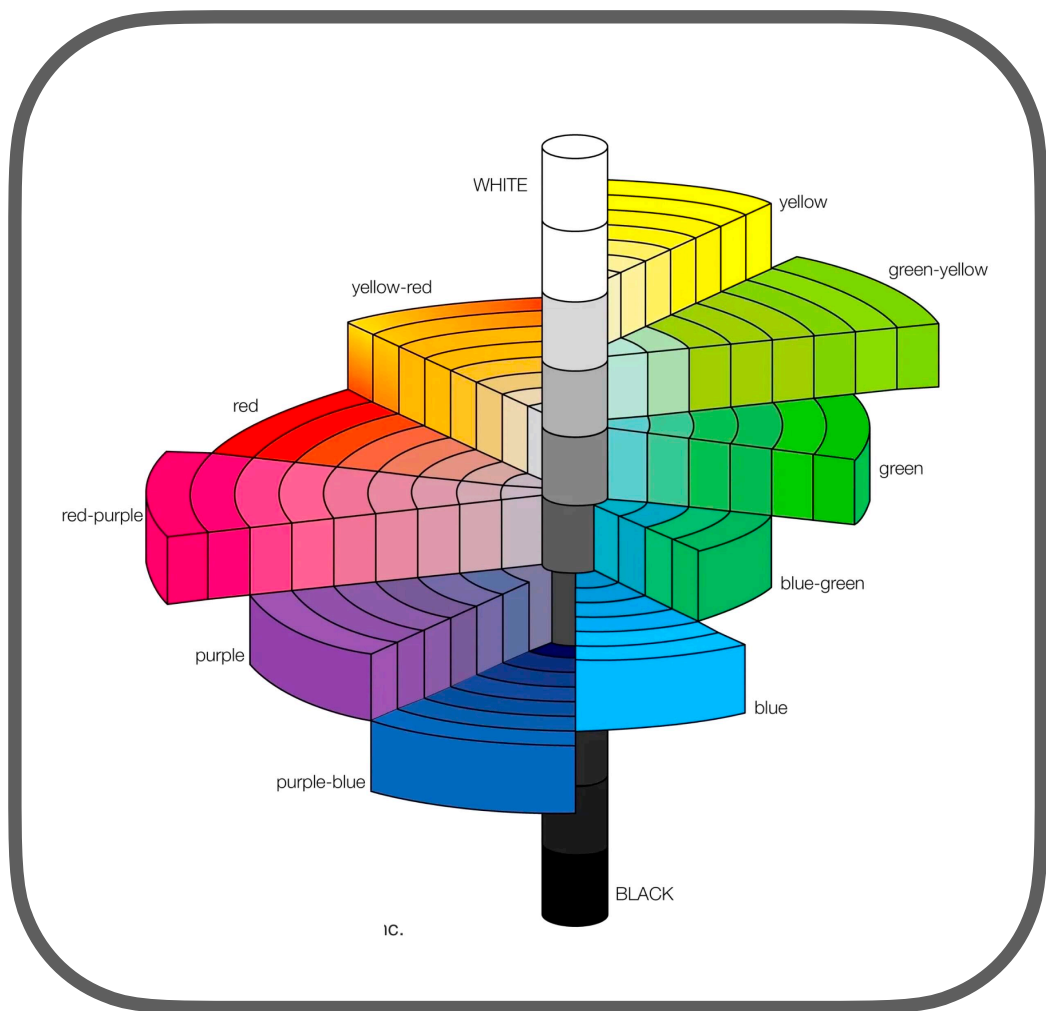

Numerous published studies by leading neuroscientists have shown that multi-sensory stimulation at gamma frequencies can induce brain wave entrainment. Our test data confirms that binaural, haptic and visual stimulation at specific frequencies increases telepathy test scores by over 300%

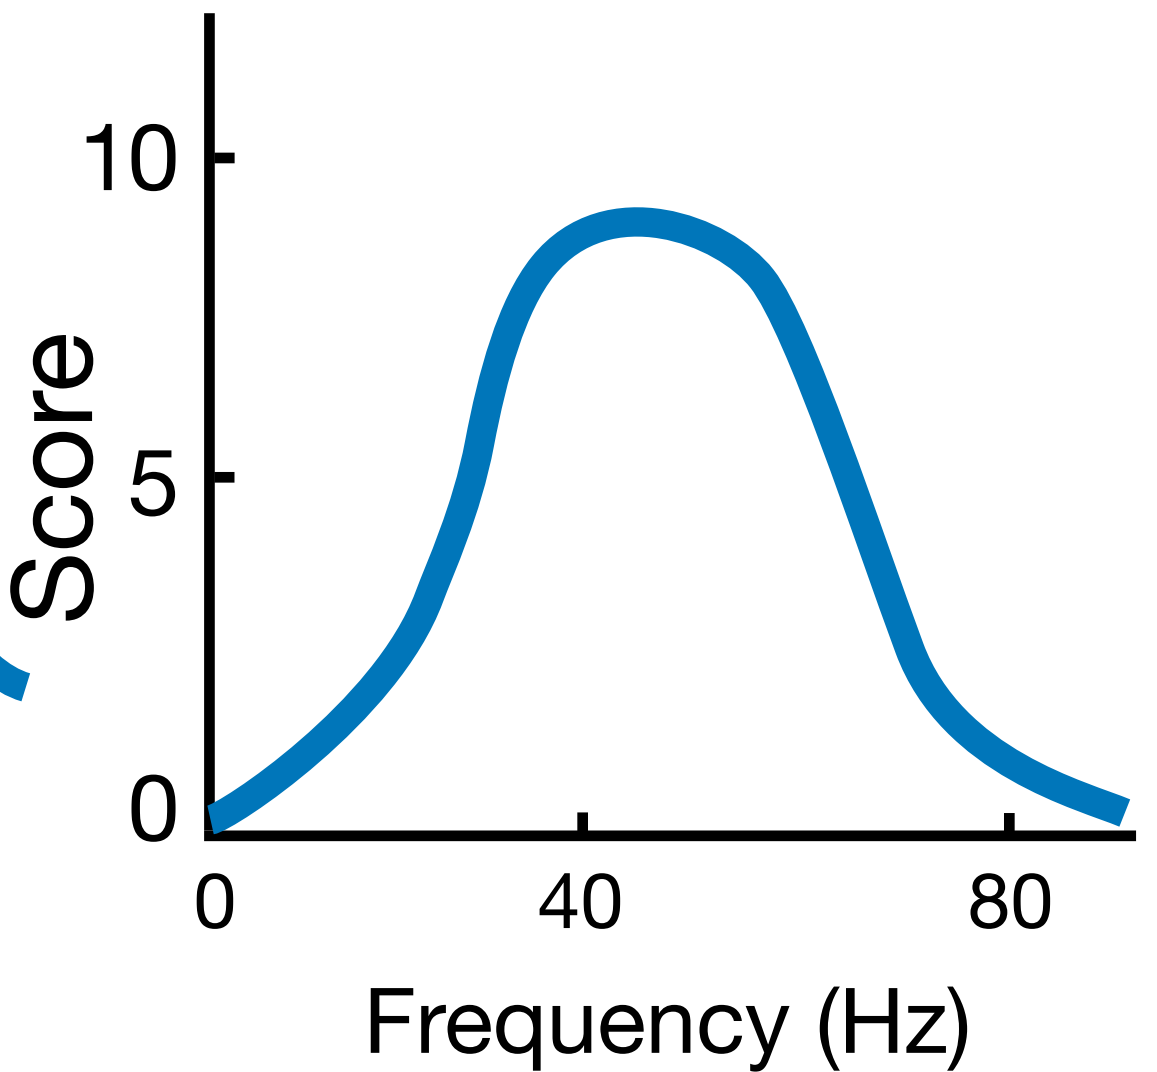

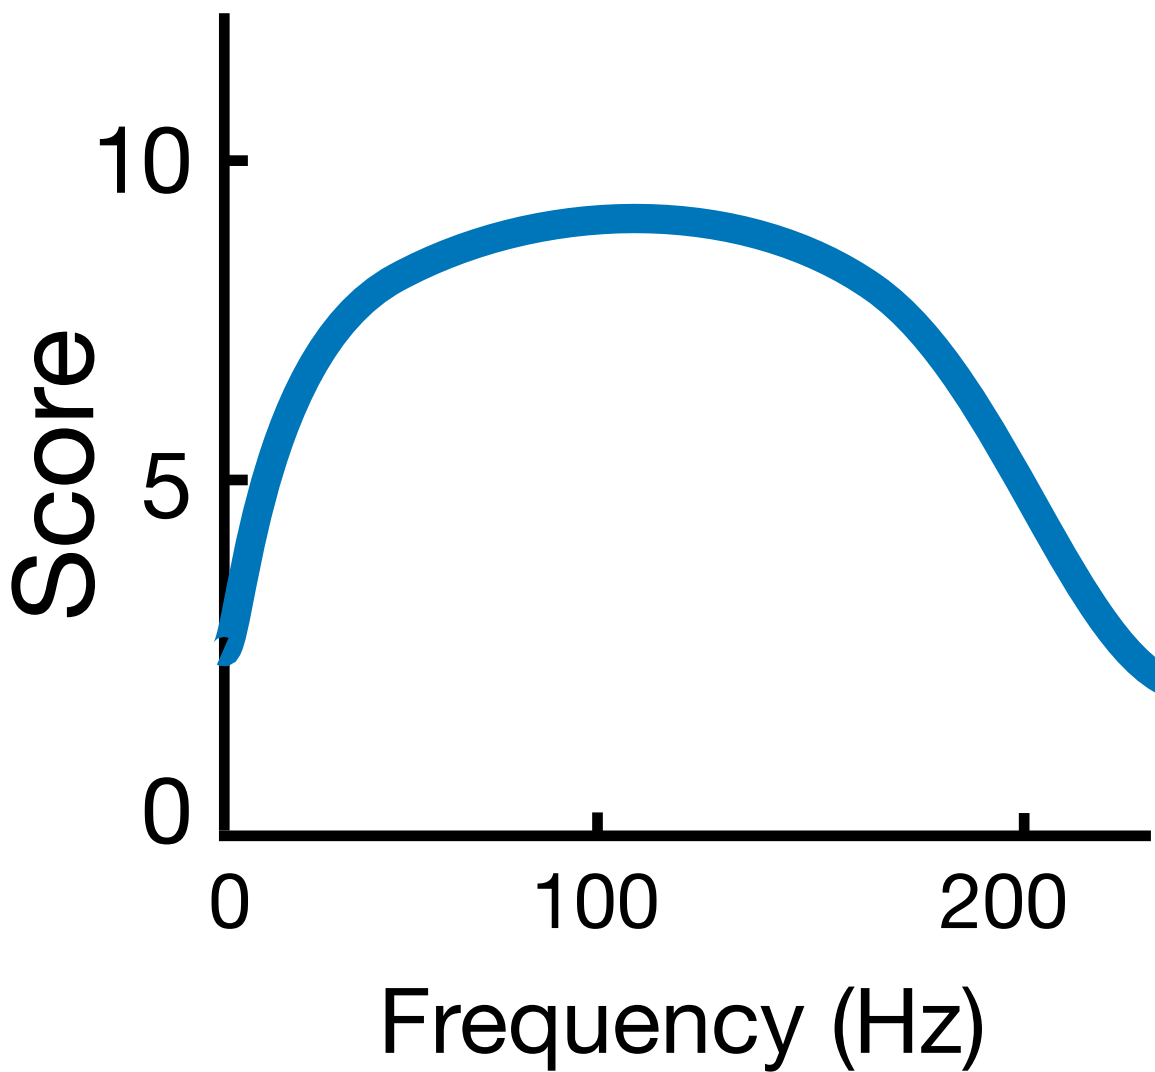

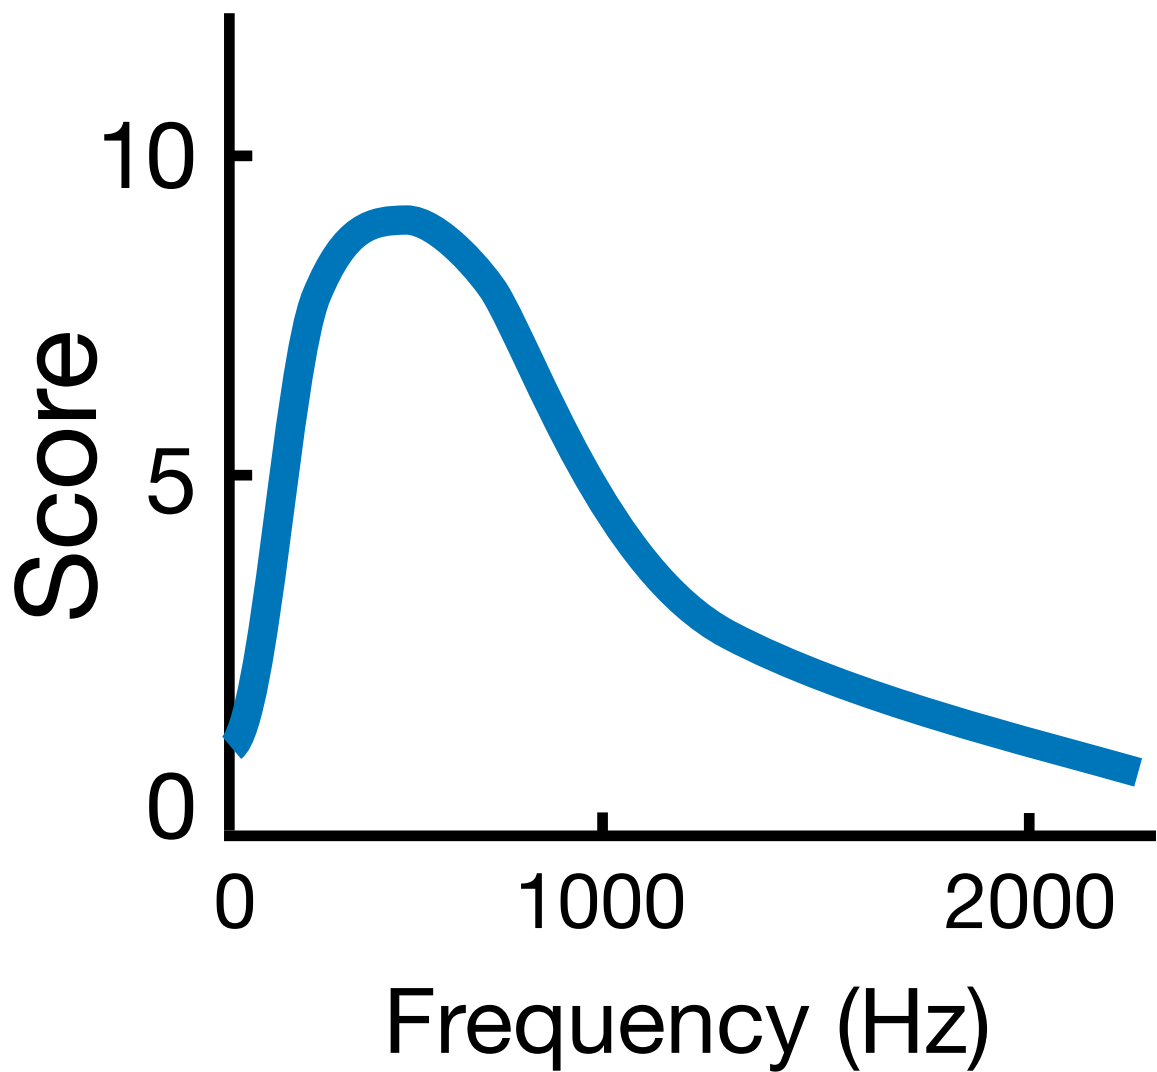

Binaural Audio
30 Hz – 800 Hz

Haptic Stimuli
20 Hz – 180 Hz

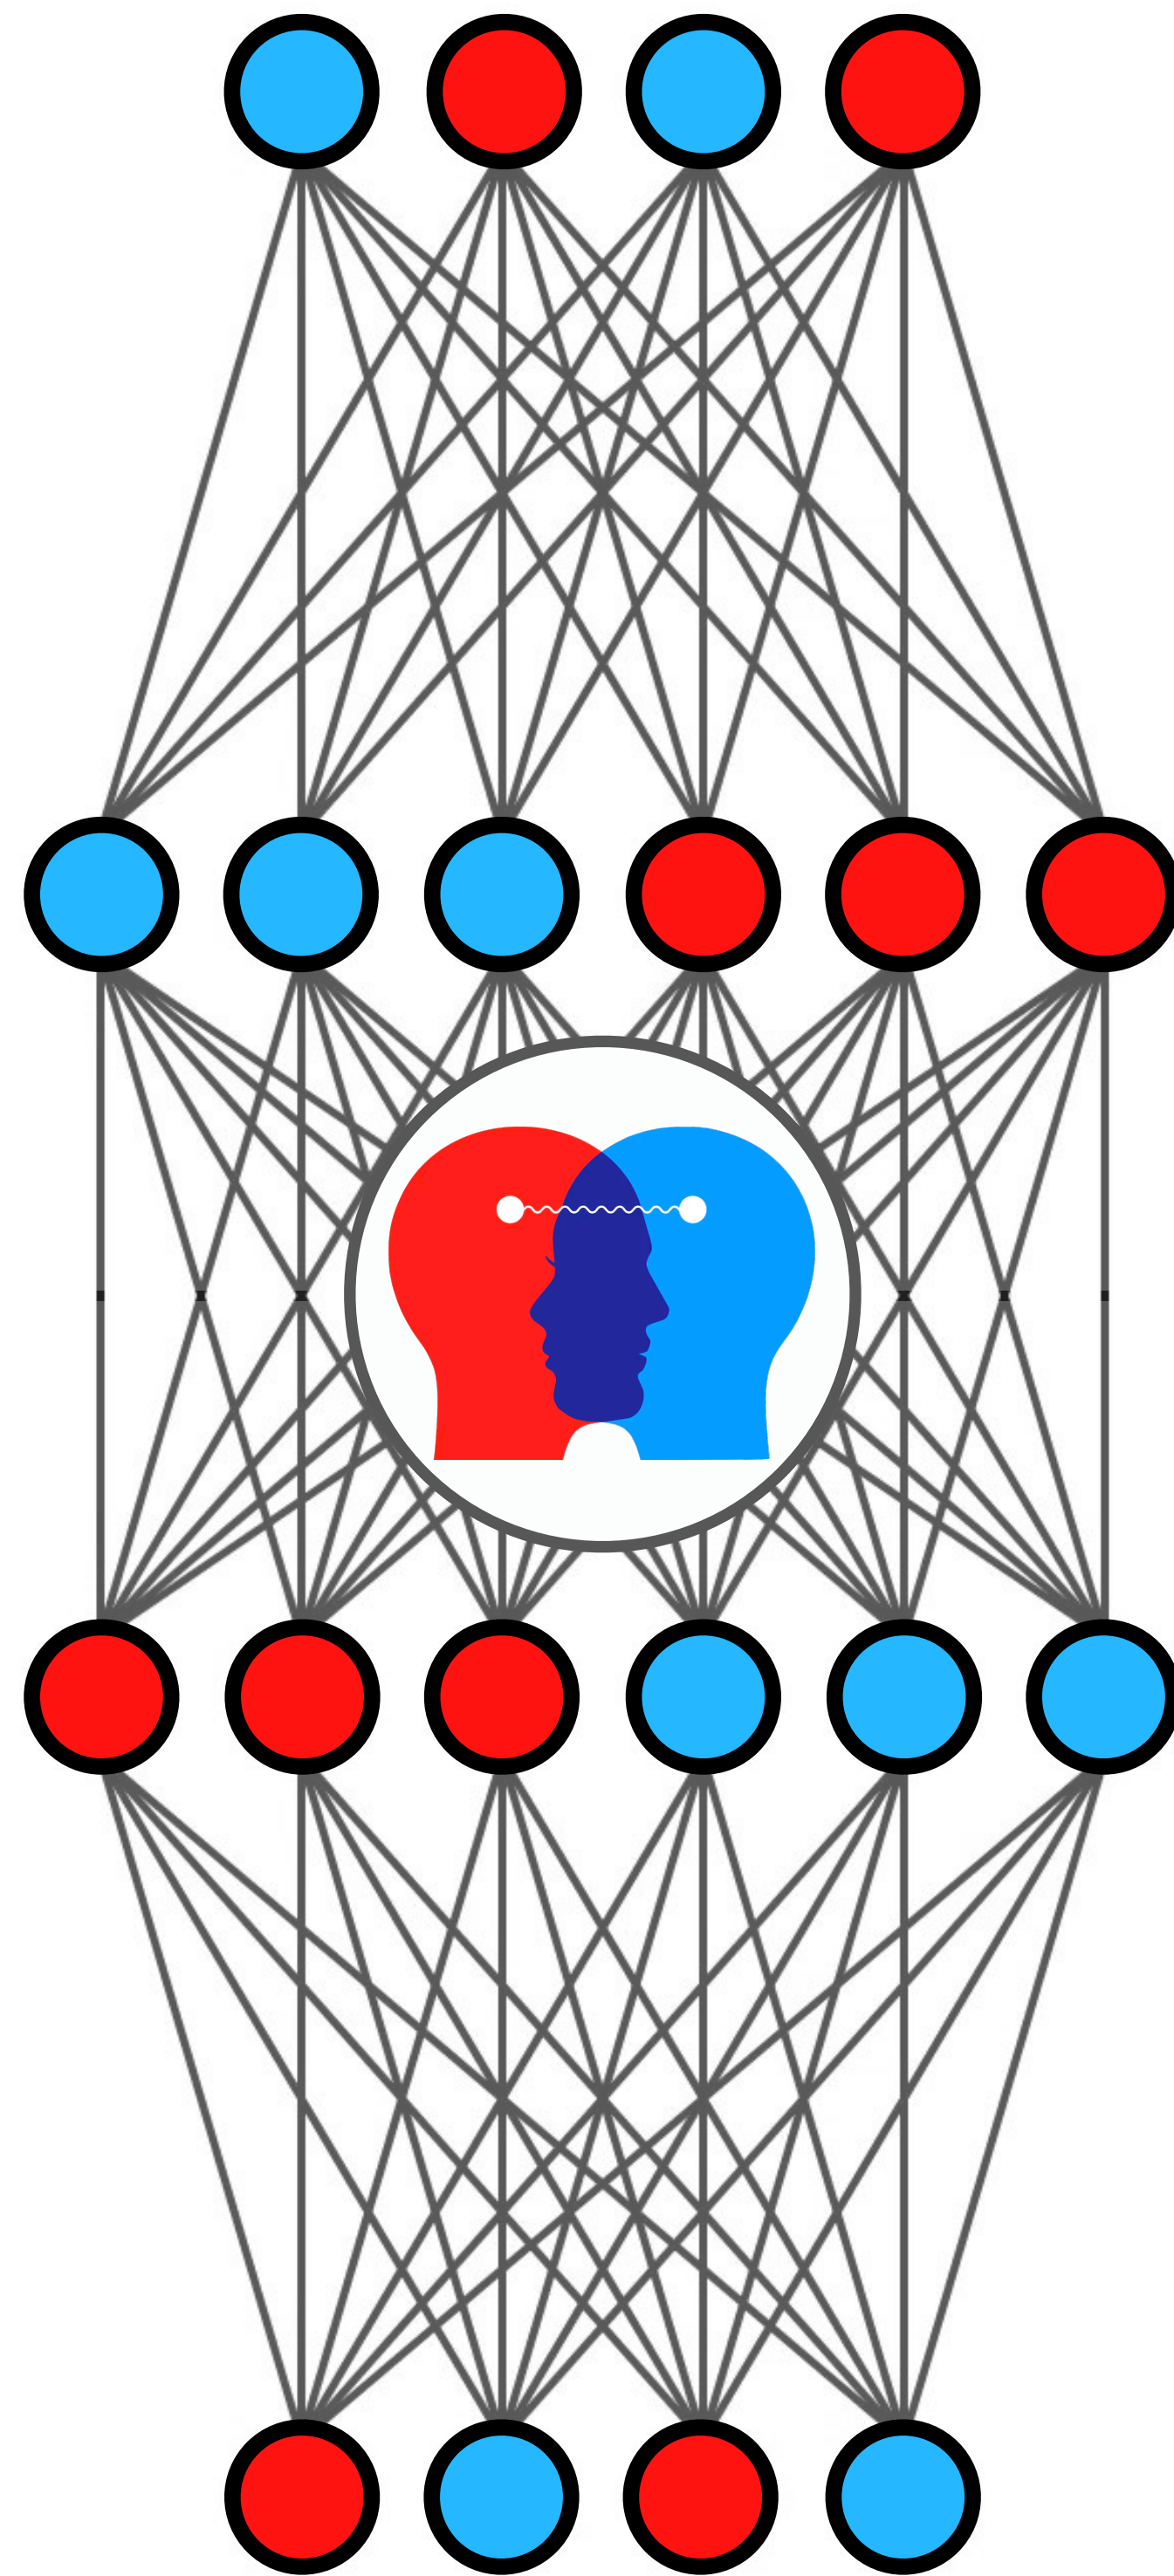

Visual Stimuli
40 Hz – 60 Hz

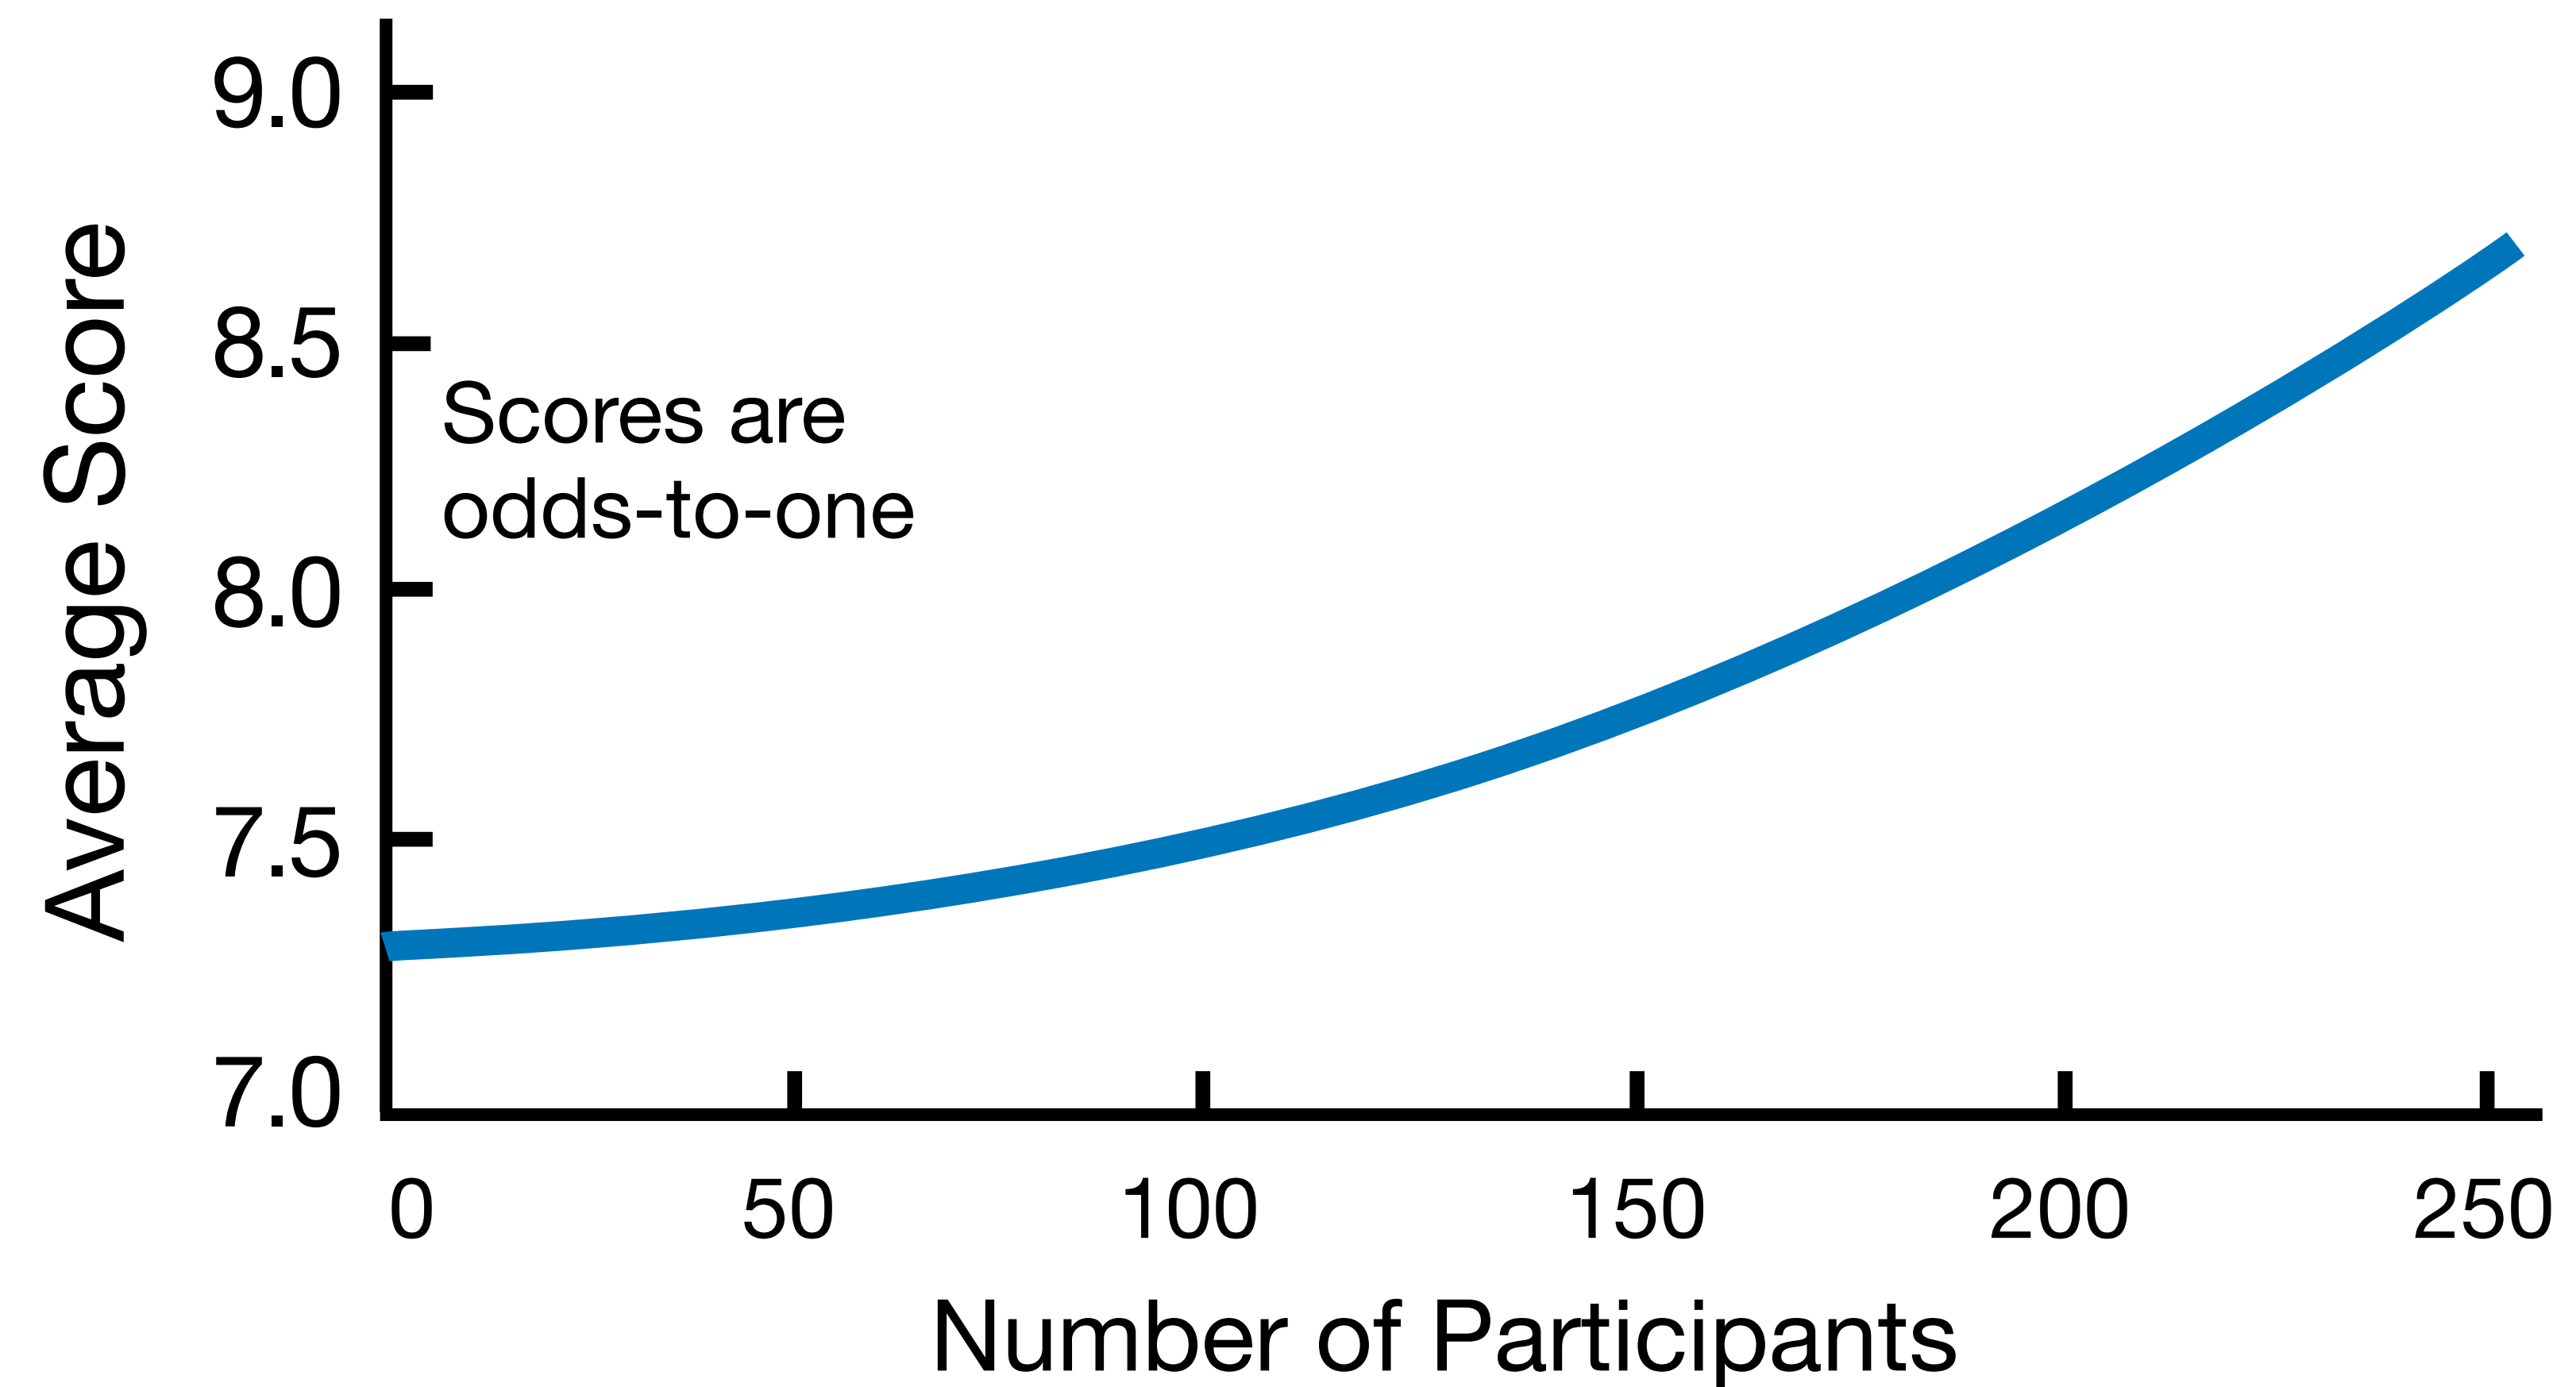

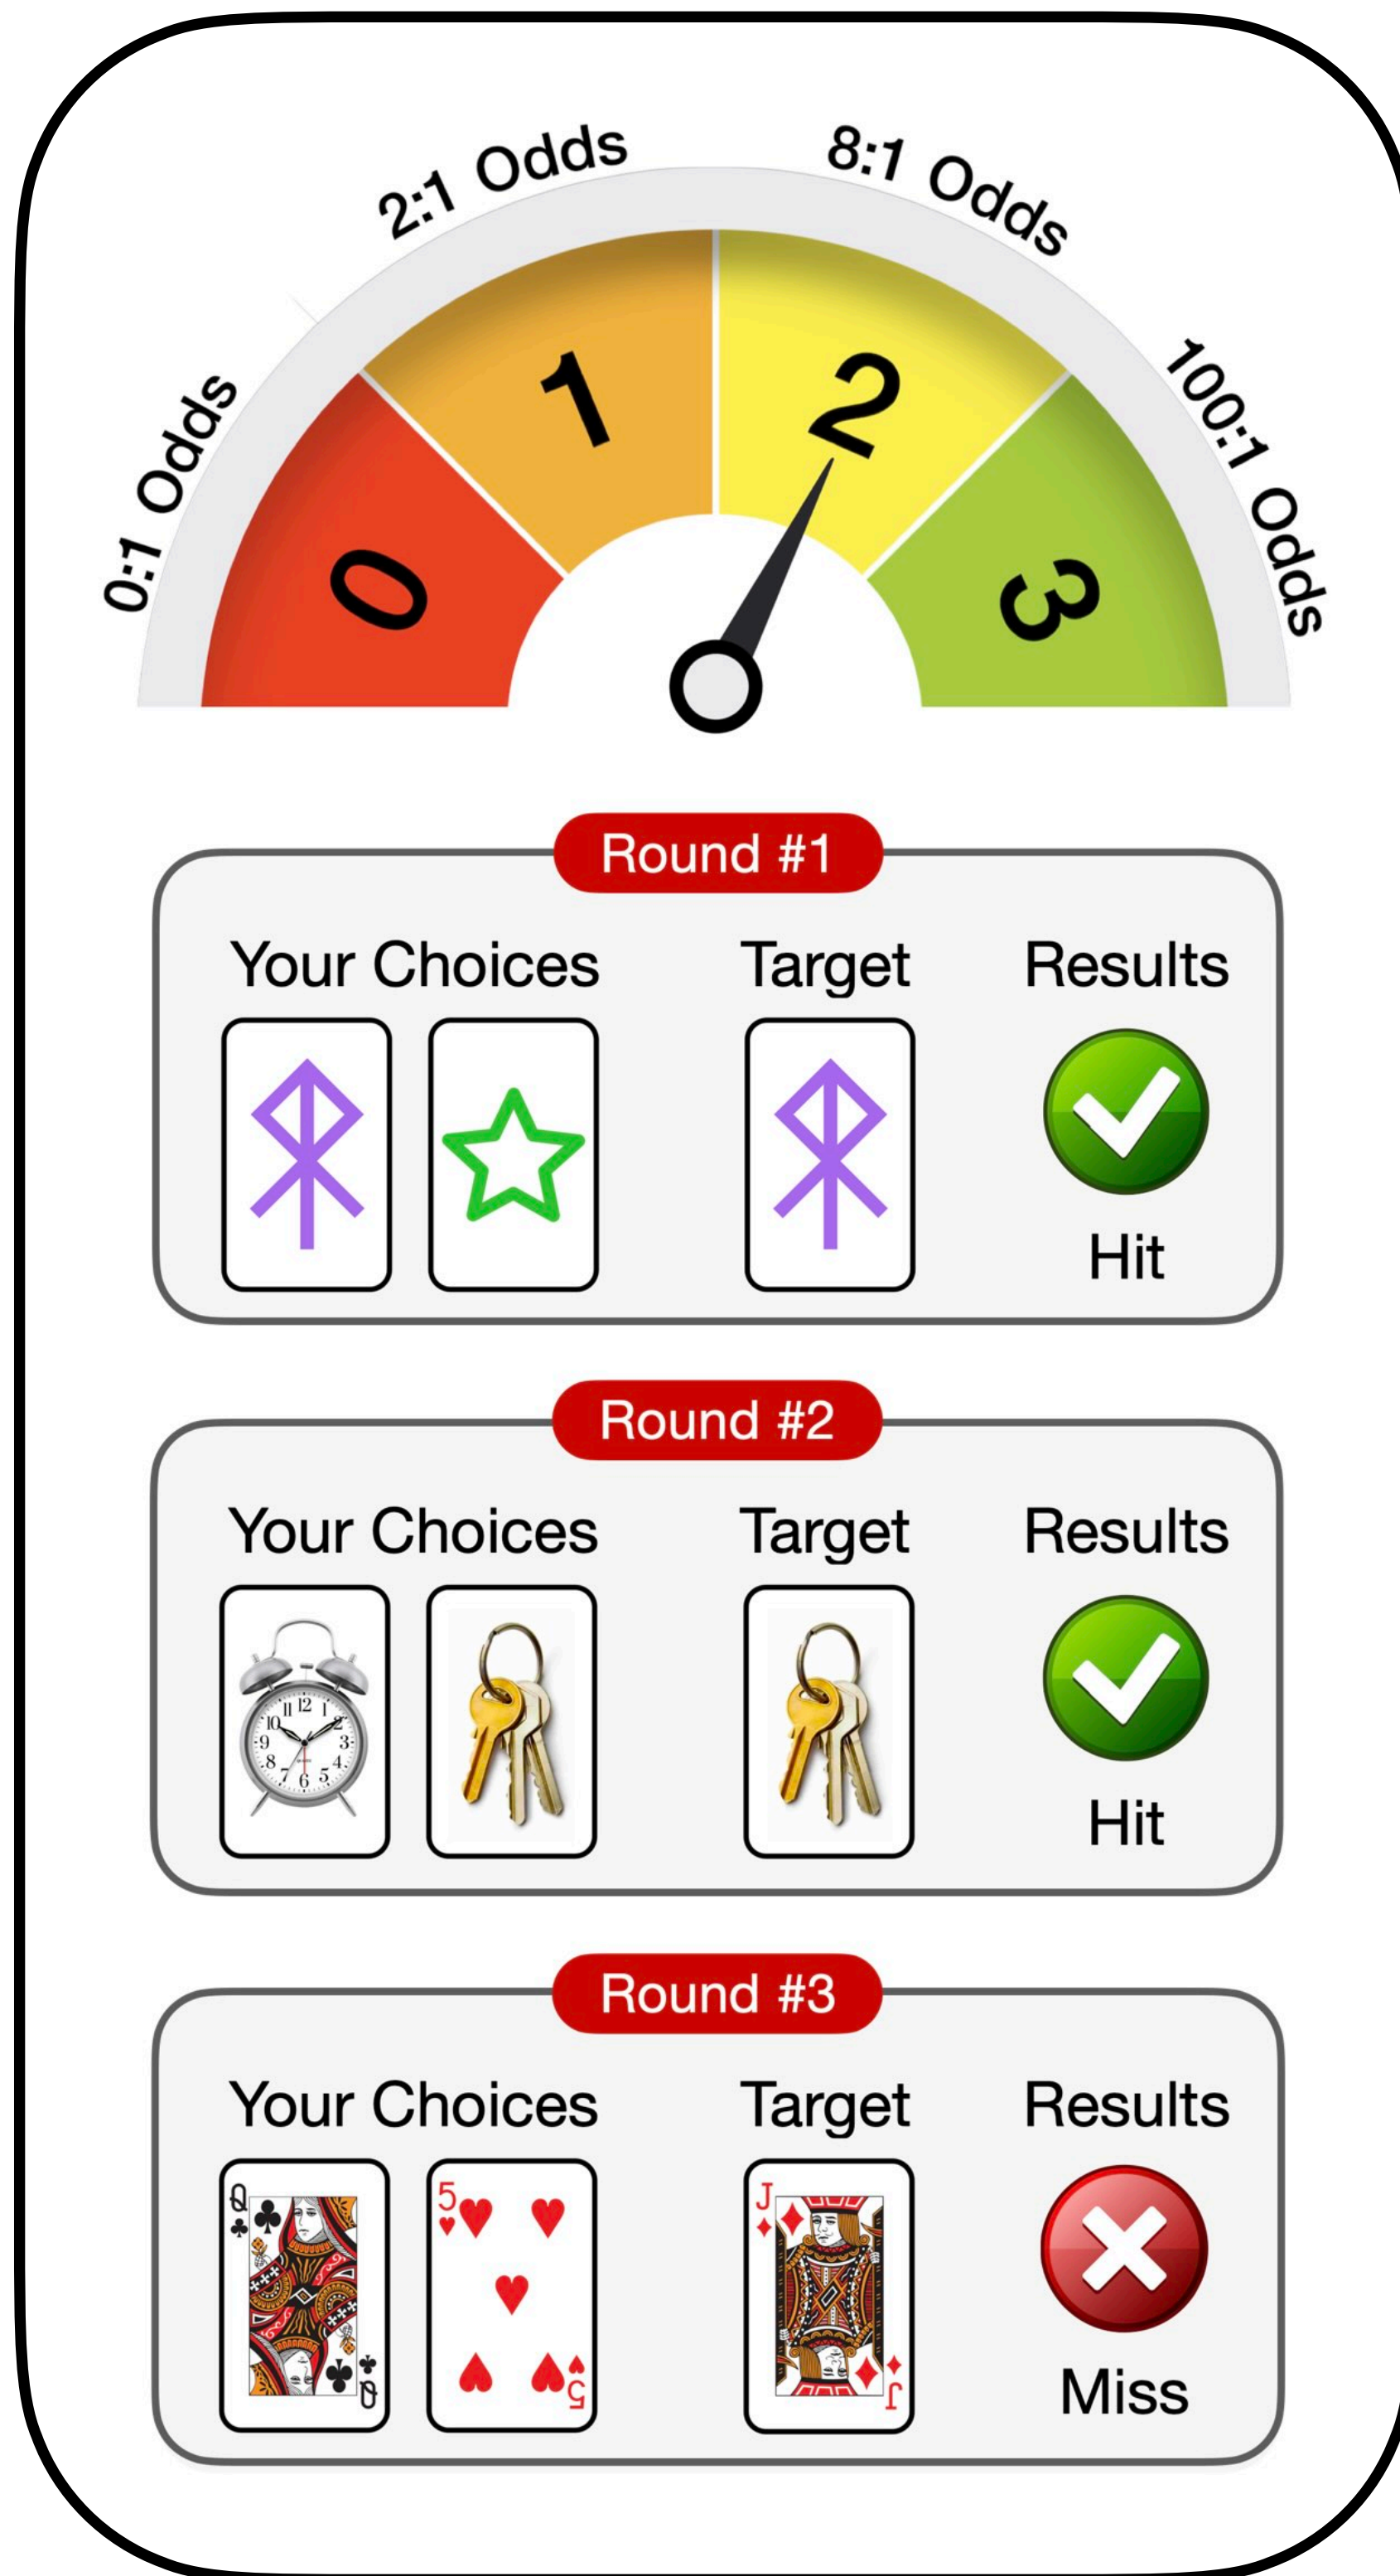

Participants who
are joined by friends
and family in tests
score 60% higher

Telepathy scores increase with more participants

Several published studies have shown a correlation between the number of participants in a telepathy test and the resulting scores. Our preliminary data shows that for every 100 additional participants in a test, the telepathy score will increase by an average of 10%.

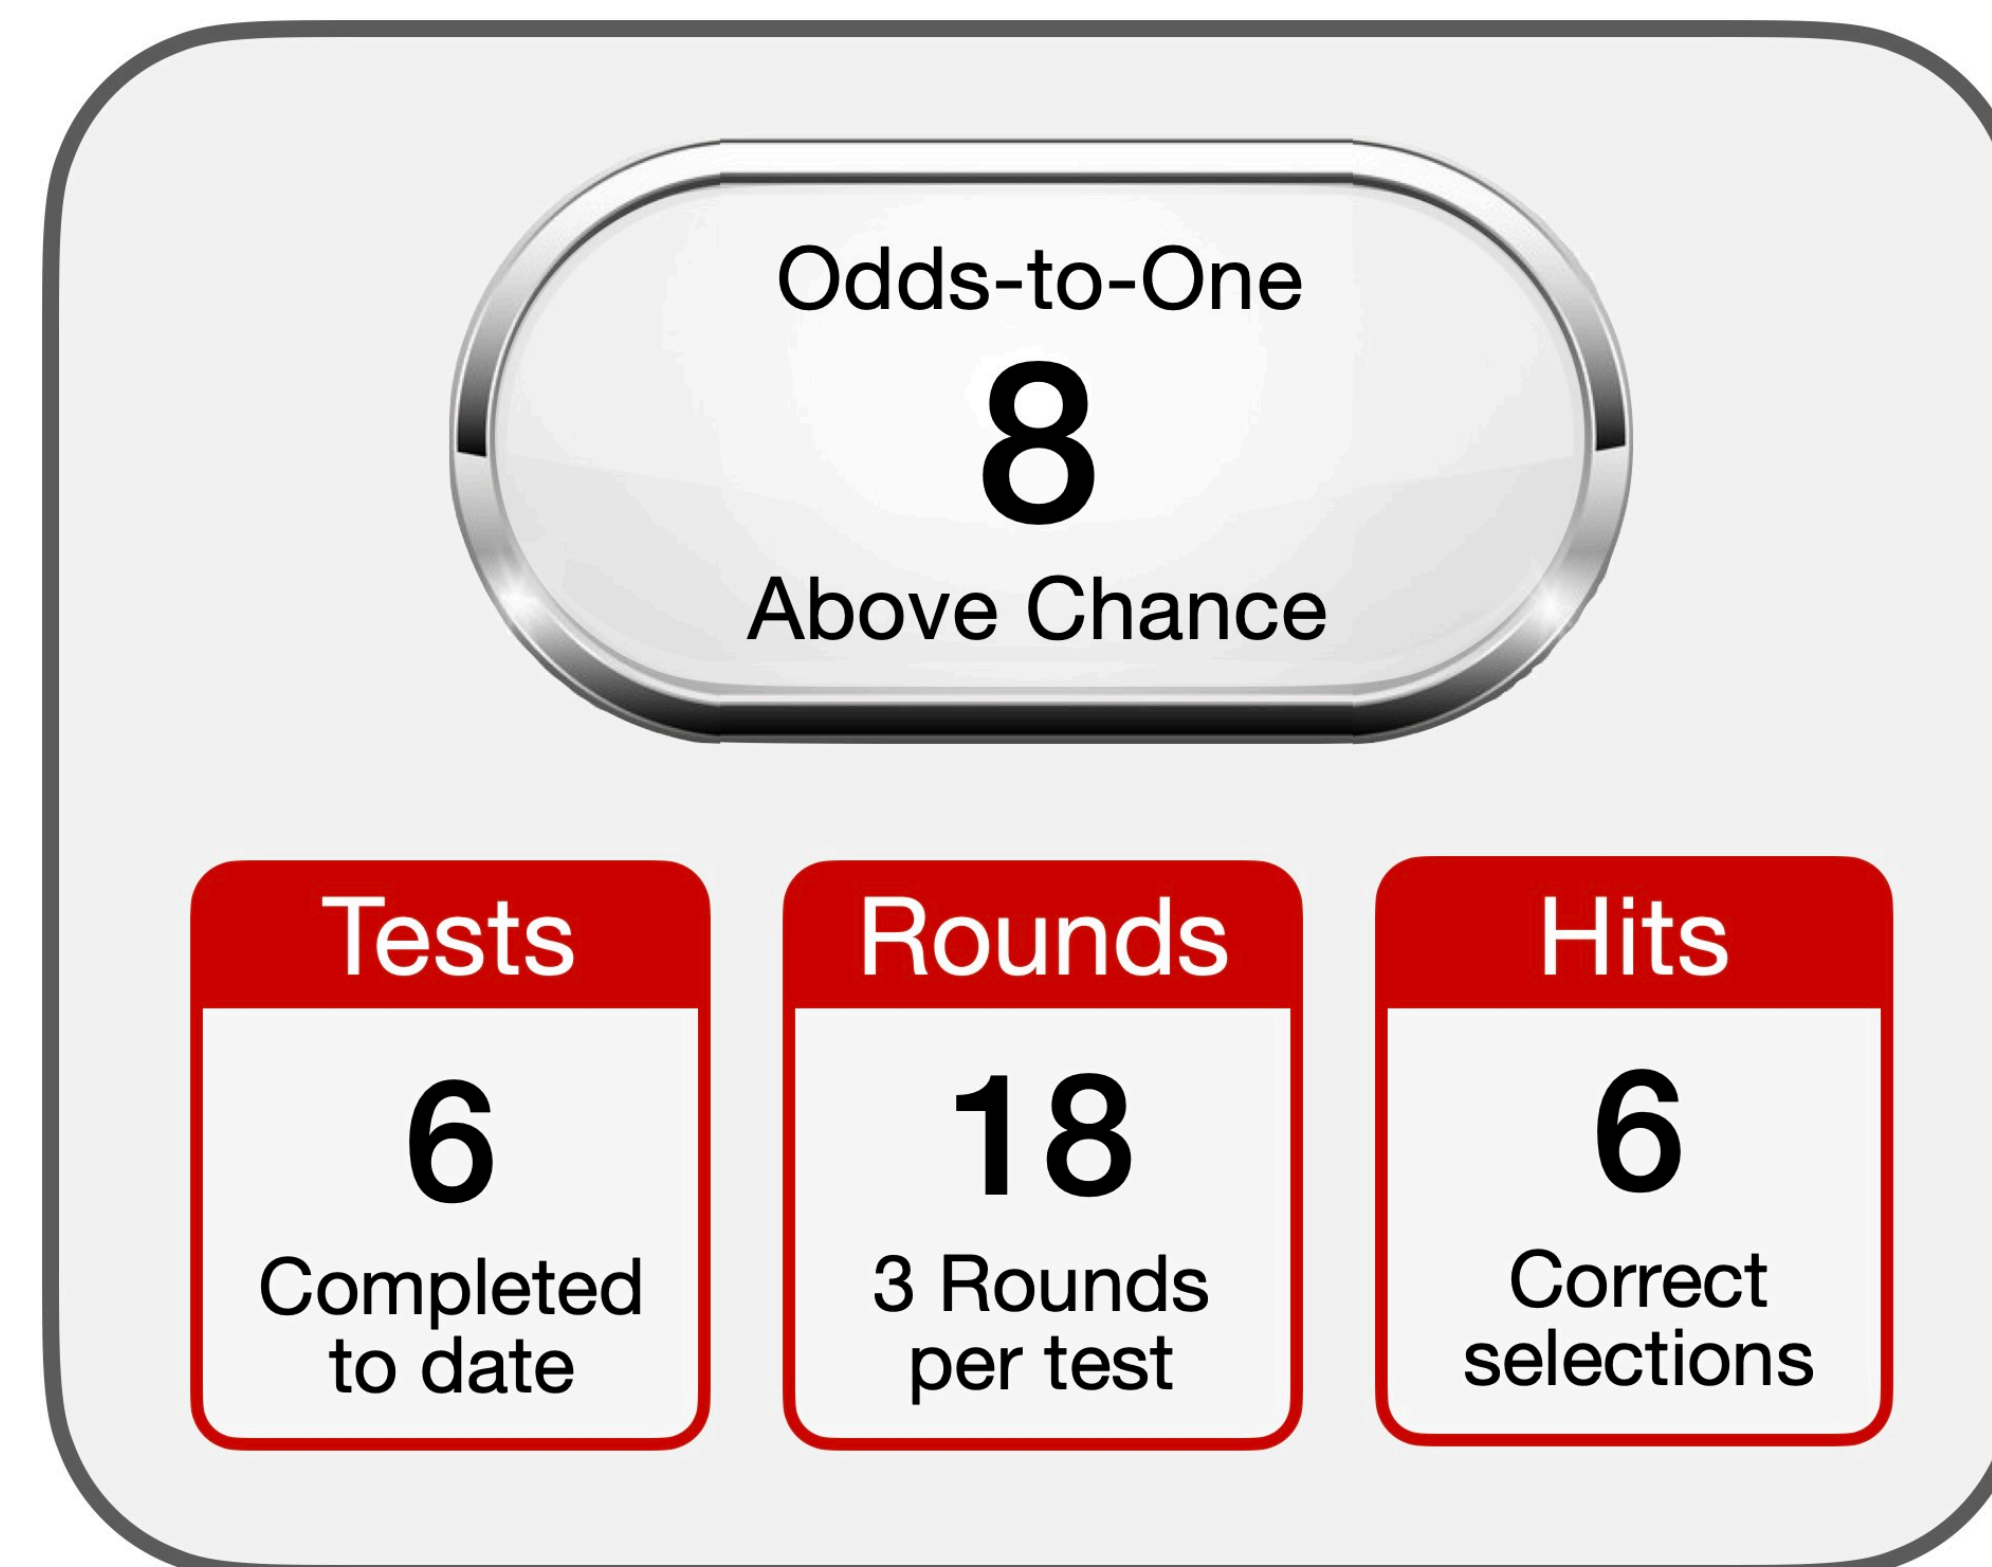

Participants take an average of 6 telepathy tests

Many people feel a sense of discovery after taking their first telepathy test, and sometimes they will repeatedly test again and again to confirm the initial results. Although some participants take dozens of tests within the first week, most people will average 6 tests with a total of 18 rounds.

Symbols and images have a significant impact on test results

The preliminary data shows a strong correlation between image type and test score, with geometric symbols having the highest ratio of correct selections. Emotional images such as animals and landmarks were the next leading visuals, with fruit and playing cards being the lowest-scoring images that were selected during tests.

Participants scored 700% higher against real people compared to simulated users

Numerous published studies on telepathy have reported that participants were much more accurate when being tested against real people, compared to a computer simulated user. Our preliminary results show that participants scored 700% higher when testing with real people versus their accuracy against simulated users.
